

Problem Statement

Bike-sharing companies generate large amounts of rental data across different time periods, rider types, and seasons. However, without proper analysis, it is difficult to understand usage patterns, revenue generation, and overall profitability.

The objective of this project is to analyze bike-sharing data from multiple years by combining datasets and integrating cost information. The analysis aims to calculate key business metrics such as **revenue and profit**, while also identifying patterns in rider behavior based on factors like **season, weekday, and hour of the day**.

By transforming and analyzing the data using **SQL in SQL Server Management Studio (SSMS)**, this project seeks to provide insights that help understand rider demand, evaluate financial performance, and support data-driven decision-making for bike-sharing operations.
